Learning disability

SUMMARY

Background: Whilst there is a need to develop the research base within learning disability nursing it is also significant that currently there is little published data as to how research is taught to this group of nurses.

Objectives: To increase understanding of how research is currently taught to learning disability nurses within the UK.

Design: A survey design was used.

Setting: The research was undertaken at a conference held in the UK in March 2014.

Participants: 310 learning disability nurses attending the conference of which 212 completed the free text question. This comprised student nurses (n = 158), registered nurses working in practice settings (n = 25) and registered nurses working in educational institutions (n = 24). Five participants did not specify their background.

Methods: Participants were invited to complete a questionnaire that included a free text question regarding the teaching of research to learning disability nurses: it is the responses to this question that are reported in this paper. Responses were transcribed and thematically analysed.

Findings: Eight themes emerged: Teaching approach – the good and the bad; finding the right level; right from the start; we need more time; generic versus specialist; there's not enough; getting research into practice; and what should we focus on?

Conclusions: Variations exist in terms of the timing of research education, the teaching approaches used, and hence the quality of student experience. Of particular concern is the apparent gap between research teaching and the use of research in practice, and the reported lack of support for research within practice settings. However, enthusiasm for research is evident and hence recommendations are made both to enhance teaching and to strengthen links with practice.

Introduction

Priorities for the development of the learning disability⁶ (LD) nursing profession within the UK are set out in *Strengthening the Commitment*

⁶ In this paper the term learning disability (LD) has been used as this is the current terminology used to describe nurses working with this group of people within the UK. It is recognised, however, that international readers may be more familiar with the term intellectual disability and in this paper these two terms should be viewed as interchangeable.

(Scottish Government, 2012) where two recommendations relate to the use of evidence in practice and the development of research in this field of nursing practice. Fundamental to the achievement of these recommendations is a workforce that is able to use evidence to underpin their practice and able to contribute to the production of new knowledge. However, currently little information exists regarding how research is taught to LD nurses. This paper seeks to address this deficit by reporting the findings of free text question within a wider survey concerning the use of research in LD nursing.

Background

The Code of Professional Conduct (Nursing and Midwifery Council [NMC], 2015) requires all nurses to base their practice on the best available evidence hence practitioners need to have an awareness of how to access research, critically evaluate it, and apply it to practice settings. However, the available literature is inconclusive in terms of how best to teach research (Hek and Shaw, 2006).

The value of research teaching has been questioned by some nursing students (McCurry and Martins, 2010) and some find learning about research difficult leading them to view this subject less positively than other subjects within the curriculum (Thomson et al., 2014). Bonsaksen (2014) suggests that the perceived/actual divide within academia between teaching and research (with few staff engaged in research) can reinforce this view by leading students to believe that research is an activity undertaken by only a few, and hence it is not relevant to them.

How best to teach research to under-graduate nurses is an issue of international concern (Irvine et al., 2008). Healy and Jenkins (2009), speaking more broadly of undergraduate research teaching, argue that it should be mainstreamed and integrated into all of the curriculum rather than being a separate subject: this supports students to engage with the subject and values the contribution of all staff (rather than just those who are research focused). Embedding research within all of the nursing curriculum rather than just in specific 'research classes' and the use of enquiry based learning to enable students to access, appraise, and apply research to clinical settings is also recommended by Christie et al. (2012).

Relevance to practice is important for nursing students and Newton et al. (2010) argue that there needs to be support for research within practice settings if students are to be able to develop an understanding and appreciation of evidence based practice. This requires that both educational curricula and the infrastructure within practice settings are supportive of the development of research and its application to practice (Loke et al., 2014), and that a culture is developed in which using research is the norm (Balakas and Sparks, 2010).

There can be difficulties with teaching research to mixed ability groups (Balakas and Sparks, 2010) but there is consensus that the use of experiential methods is beneficial (Irvine et al., 2008). McCurry and Martins (2010) found that students preferred the use of interactive group activities that facilitated the practical application of research skills. Elsewhere the use of peer tutors (more senior students and recently qualified nurses) to support student learning regarding research has been found to be helpful (Thomson et al., 2014). Most importantly the use of peer tutors was found to make research feel more accessible to the students since it demonstrated that it was not just something understood and undertaken by academic staff.

Nursing educators have been urged to change their focus from simply providing information about research to providing opportunities for students to gain experience of the research process (Loke et al., 2014) and it has been argued that students should be moved from being consumers of knowledge to being knowledge producers (Healy and Jenkins, 2009). Birks (2011) suggests that academics should seize the opportunities available to engage students in active, engaging and meaningful ways in research but recognise that this requires specific skills.

Whilst this literature highlights issues that may be relevant to the teaching of research to LD nurses no literature was found that specifically addressed this particular context. This paper therefore aims to address this gap in knowledge.

Methods

Data Collection

A questionnaire was developed for the purpose of this study and this was piloted with 5 registered and 5 student nurses not involved in the main study: no substantive changes were made. The questionnaire comprised predominantly fixed response questions but the focus of this paper is on the free text data collected in response to the statement: 'What do you think about how research is taught to

learning disability nurses? What is good and what needs to be improved?'

Participants were given a copy of the questionnaire at conference registration and an announcement was also provided from the stage on day one. Completed questionnaires were collected via a box available at the registration desk and members of the research team were available throughout the two days of the conference.

Sample

A convenience sample of nurses attending the Positive Choices Conference in March 2014 was invited to participate in this survey. This conference is held annually primarily for student nurses from the United Kingdom (UK) and Ireland undertaking courses in LD nursing: some registered nurses also attend. In total 498 people registered to attend the conference and of these 310 (62%) completed and returned the questionnaire. Two hundred and twelve (68% of participants) comprising student nurses ($n = 158$), registered nurses working in practice settings ($n = 25$) and registered nurses working in educational establishments ($n = 24$) completed the free text question that forms the basis of this paper. Five participants did not specify their background. Participants were each assigned a participant number and this is used for identification purposes in the discussion of findings.

Ethics

The questionnaire included an initial section that detailed the rationale for the study, how the data would be used, and mechanisms to ensure anonymity of responses. It was stated that return of the questionnaire would be taken as implying consent to participate in the study. The study was reviewed by the Faculty of Life Sciences and Education Ethics Committee at the University South Wales and received a favourable opinion.

Data Analysis

All responses were transcribed verbatim and reviewed by all members of the research team to identify recurring themes. Based on this initial review consensus was achieved and a coding frame was developed detailing key themes and associated descriptors. This was used by two members of the team (RN and MP) to independently code all of the data. Coding was then compared and a high level of agreement was noted with minor differences being resolved through discussion. To assist with retrieval of coding the raw data was then entered into NVivo and the agreed codes applied. Table 1 below details the 8 major themes and the number of excerpts coded to each theme.

Discussion of Findings

Teaching Approach: The Good and the Bad

Respondents highlighted the impact of teaching style, and the skills and knowledge of lecturers, on student engagement in research.

Table 1
Key themes.

Theme	Number of excerpts coded
Teaching approach: the good and the bad	52
Finding the right level	15
Right from the start	20
We need more time	35
Generic versus specialist	42
There's not enough	22
Getting research into practice	17
What should we focus on?	45

This lack of research was perceived as impacting both on understanding the needs of people with a learning disability and also on student academic development:

'Nice that there is LD specific research however there needs to be more research as I am preparing for my dissertation and struggled/struggling to get LD specific research. So I had to incorporate research from other fields in order to make up the 10–12 articles needed' (R57 student nurse)

'Hard to access material that is appropriate' (R178 student nurse)

However, it needs to be remembered that wider nursing research and wider LD research may also be relevant to improving the quality of life for people with learning disabilities. LD nurses need, therefore, to have the skills and confidence to access such research.

For one participant it was important that research should be developed by those who are working directly with people with learning disabilities:

'I believe that LD research could be driven more than it is currently being. It could be improved by more LD research being carried out by LD professionals who work directly with people adults/children with LD' (R296 registered nurse)

Getting Research Into Practice

All student nurses in the UK are required to spend 50% of their time in university based study and 50% in practice settings and it is essential that learning about research is continued within practice settings (Loke et al., 2014). A number of participants recognised the importance of this:

'We need to continually develop to link theory to practice to be able to give the best care to our clients' (R244 student nurse)

'I find it hard to understand in university. I learn it better when it is being used in practice' (R293 student nurse)

Participant responses, however, suggest that there are challenges that limit the extent to which this occurs:

'Research often taught in a theoretical classroom setting and should be taught in a more practical way within the clinical area' (R53 registered nurse – education)

'I don't feel that there was enough emphasis on using the most up to date research and practicing in accordance with it' (R74 student nurse)

'...more support for students, focus on evidence based practice during practice placements for student LD nurses' (R288 student nurse)

However, participants also suggested a more general lack of support for research within practice settings at both individual and organisational levels:

'In training taught about its role in informing practice. Post-graduating not really done much in practice, very much 'on your own', no support. Thus lack of energy and enthusiasm to keep up with research despite requirement by NMC to be up to date in practice ...' (R182 registered nurse)

'When discussing research in practice staff didn't seem to value it being carried out in their practice area.' (R174 student nurse)

'It is very hit and miss. Some nurses struggle with the implementation of research in their practice and recognising that they are interdependent' (R190 registered nurse)

The dissemination of research was identified as being more than just the responsibility of individual practitioners, rather there is a wider service/organisational duty to facilitate this. Also, it was suggested that there needs to be more encouragement and opportunity for practitioners to be involved in research.

'There needs to be more opportunities to add and get involved in research in practice. Research findings need to be filtered through organisations in interesting and innovative ways' (R219 student nurse)

Many of these responses suggest that the support for research in practice settings (Newton et al., 2010) may be lacking and that work is required to develop a culture in which using research is viewed as the norm (Balakas and Sparks, 2010).

What Should We Focus On?

A number of participants proposed strategies that could be used to enhance the teaching of research within LD nursing for example providing opportunities for students to become active participants in the research process rather than just passive consumers of research lectures:

'It is taught as something we need to understand and how to critique it. However, there is little suggestion that we should somehow be involved in doing it' (R196 student nurse)

'I don't think students are given enough time and opportunity to develop these skills and there is rarely opportunity to carry out research' (R61 registered nurse – education)

'We are taught how to use, critique and apply but a lack of focus on implementing our own research' (R33 – registered nurse)

'Being involved in current 'real' research project has helped me' (R264 student nurse)

These responses suggest that the teaching approaches advocated by Loke et al. (2014) and Healy and Jenkins (2009) might be beneficial.

The importance of role modelling was also recognised: students need to be able to see lecturing staff as being research active:

'Students need to see academic staff engaged with research/working in partnership with students and mentors' (R31 registered nurse – education)

Conclusions

This study used a convenience sample hence its composition may not be reflective of the wider LD nursing profession. Whilst the overall response rate for the survey (62%) is positive it is not possible to assess how those who chose not to participate were similar to, or differed from, those who did and the data presented here relates to only one question in the survey. Finally the participants all come from one nursing speciality within one country. All of these factors limit the extent to which it is possible to generalise from the findings. However, the aim of the research question was to develop an understanding of an area where no published data existed rather than to generalise. In addition the findings both reflect and add to the wider literature regarding the teaching of research to nurses and hence may have relevance outside

of both the speciality and the country. This being the case there are some conclusions that can be drawn.

The findings of this study suggest that within LD nursing currently there is variation in the timing and amount of research teaching, the teaching approaches used, and hence the quality of student experience. Of concern is that the links between research and practice often appear to be weak and some participants reported a lack of support for the use of research within practice settings. Whilst this may be a reflection of practice constraints it needs to be addressed both to improve the quality of student learning opportunities and, most importantly, to improve the quality of support provided for people with learning disabilities. However it was encouraging to note an interest in, and enthusiasm for, research amongst participants which provides a good base from which to develop.

Some strategies emerged from the study findings as being potentially useful in taking forward this agenda: the introduction of research early in nursing courses, the integration of research into all modules, the use of teaching methods that actively engage students, and (where possible) providing opportunities for students to become involved in research studies. All of these strategies can be taken forward by staff working within universities although it is recognised that in some instances staff may require support to ensure that they are able to deliver a 'research active curriculum' (Healy and Jenkins, 2009:3). However, in conjunction with this, there is clearly a need for university based staff to engage with, and support, not only practitioners working in clinical settings but also with the organisations for whom they work in order to work towards achieving a culture in which using research is the norm (Balakas and Sparks, 2010).
